Cramming more components onto integrated circuits

With unit cost falling as the number of components per circuit rises, by 1975 economics may dictate squeezing as many as 65,000 components on a single silicon chip

By Gordon E. Moore

Director, Research and Development Laboratories, Fairchild Semiconductor division of Fairchild Cemera and Instrument Corp.

The future of integrated electronics is the future of electronics itself. The advantages of integration will bring about a proliferation of electronics, pushing this science into many new areas.

Integrated circuits will lead to such wonders as home computers—or at least terminals connected to a central computer—automatic controls for automatics, and personal portable communications equipment. The electronic wristwatch needs only a display to be feasible today.

But the biggest potential lies in the production of large systems. In telephone communications, integrated circuits in digital filters will separate channels on multiplex equipment. Integrated circuits will also switch te lephone circuits and perform data processing.

Computers will be more powerful, and will be organized in completely different ways. For example, memories built of integrated electronics may be distributed throughout the

The establishment

Integrated electronics is established today. Its techniques amost mandatory for new millitary systems, since effective liability, size and veight required by some of them is a chievable only with integration. Such programs as Apollo, for manned moon flight, have demonstrated thereliability of integrated electronics by showing that complete clicuit functions are as free from failure as the best individual transitions.

Most companies in the commercial computer field have minies in design or in early production employing integrated electronics. These machines cost less and perform better than those which use "conventional" electronics.

Instruments of various sorts, especially the rapidly increasing numbers employing digital techniques, are starting to use integration because it outs costs of both manufacture and design.

The use of linear integrated circuitry is still restricted primarily to the military. Such its degreted functions are expensive and not available in the variety required to satisfy a major function of linear electronics. But the first applications are beginning to appear in commercial electronics, paticularly in equi pment which needs low-frequency amplifiers of small size.

Reliability courts

In almost every of strated high reliability tion—low compared fers reduced systems performance has been

Reduced cost is a electronics, and the othe technology evolve larger circuit function For simple circuits, the proport ional to the nu equivalent piece of semiconductor in the equivalent package containing more components. But as components are added, decreased yields more than compensate for the increased complexity, sending to raise the cost per component. Thus there is a minimum costat any given time in the evolution of the technology. As present, it is reached when 50 components are used per circuit. But the minimum is rising rapidly while the entire cost curve is failing (see graph below). If we look ahead five years, a plot of costs suggests that the minimum in cost per componentinglish the expected in circuits with about 1,000 components per circuit (powking such circuit functions can be produced in moderate quantities.). In 1970, the manufacturing cost per component can be expected to be only a tenth of the present cost.

The complexity for minimum component costs has increased at a race of soughly a factor of two per year (see graph on next page). Certainly over the short term this race on be expected to continue, if not to increase. Over the longer term, the rate of increase is a bit more uncertain, although there is no reason to believe it will not remain nearly constant for at least 10 years. That means by 1975, the number of components per integrated circuit for minimum cost will be 65,000.

I believe that such a large circuit can be built on a single
